Students of the L.N. Gumilyov Eurasian National University, Nur-Sultan, Kazakhstan Research Supervisor - A.B. Ospanova

Annotation. The work includes a set of works aimed at optimizing certain administrative processes of Windows operating systems. A classification of administration tasks has been developed in order to determine both labor-intensive and routine administration tasks, as well as tasks requiring and allowing automation. A comparative analysis of administration tools, including built-in and open source utilities, is made based on pre-selected criteria. A plugin for the Process Hacker utility has been developed and deployed, which allows creating and control of the list of allowed and conditionally prohibited programs in Windows 7 SP1, Windows 8, Windows 10 operating systems.

Keywords: Windows, Open Source, Process Hacker, System Management Services I Introduction and the problem statement

A large percentage of the PCs (workstations) used nowadays in organizations runs Windows operating systems. The level of qualification of a system administrator, as well as the tools used to control and configure operating systems, corporate networks, and peripheral devices, are largely determining factors for the security, fault tolerance, and reliability of an organization's infrastructure. Built-in administration tools are not always convenient for effective management of system processes, and may not possess configurable capabilities for performing both routine and special administration tasks ([1]). There are many third-party specialized utility programs, both open source and commercial ([2-4]). However, the specific tasks of administration and security, the emergence of new technologies give rise to new administrative tasks and cause the need for their automation. At the same time, there are requirements for the system administrator to be acknowledged with scripting languages, also to be able to work with programs with a command-line interface ([5-7]).

The problem of creating personalized tools for advanced administration of operating systems can be reduced to solving the following main tasks:

1) Studying of the Windows device, as well as API tools from the point of view of system programming in order to create utilities and drivers with enhanced privileges;

Types and methods of the conducted research:

- Research and analysis (classification of administrative tasks, determination of the actual task, comparative analysis of utilities and built-in administrative tools);
- Programming (development of a plugin with an automatic launch for the Process Hacker utility, capable to create and control lists of allowed and conditionally prohibited programs in the system);
- Debugging and testing the driver and the plugin in different versions of operating systems, taking into account the Windows policies.

II Windows administration tools and instruments

System administration of Windows operating systems includes the following tasks:

- Installing, configuring, and updating various types of software;
- Connecting and configuring peripherals;
- Launching and configuring system services (system configuration);
- User account management, technical support;

- Process Management;
- Resource allocation;
- Monitoring of the system operation, ensuring information security, fault tolerance;
- Providing data backup, performing data recovery.

Windows Built-in Windows administration Tools

In later versions of Windows, there are built-in tools for administration and computer management - the "Administration" section. Windows 10, 8.1, and Windows 7 are well-endowed with useful built-in system utilities:

- "System configuration". Allowing to configure the operating system boot settings.
- "System Information".
- "Troubleshooting Windows".

"Computer Management". Provides tools such as: Task Scheduler; View Windows events; Resource Monitor; Disk Management; System Stability Monitor; Disk cleanup; Windows Memory checker.

• "Task Manager".

Third-party utilities for the operating system administration

Utilities are considered:

- Advanced IP Scanner Local network scanner,
- NetWrix Inactive Users Tracker search for inactive accounts,
- WinAudit Freeware Operating system audit,
- Performance Analysis of Logs system performance analysis,
- Free Active Directory Tools free analogue of Active Directory,
- Comodo Time Machine rollback of the operating system,
- System Explorer monitoring running processes and services, checking for threats and rootkits,
 - Daphne monitoring the system operation, stopping processes on a schedule,
- *MiTeC Task Manager* monitoring running processes and services, viewing open files, launch dates,
- *Process Explorer* (a utility from Microsoft's SysInternals) monitoring of running processes and services, disks, and processor operation,
- *Process Hacker* free and open-source program that provides considerable administration capabilities for Windows operating systems, while there is an API for developing personalized plugins.

Table 1 provides a brief comparative analysis of the *Process Explorer* and *Process Hacker* utilities.

Table 1. Comparison of the Process Explorer and the Process Hacker utilities

	Common characteristic	Process Hacker	Process Explorer
Installation	Both programs have a	easy to launch and run	Acceptance of the terms and
	portable version		conditions is required
Checking for		included	not applicable
updates			
Tray icons	Both programs provide the	By default, shows the	By default, shows only the

III Development of the ProcessDeepManage plugin

Process Hacker and Plugins creation

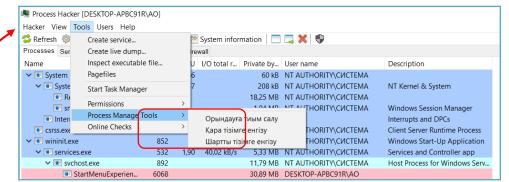

The source code of ProcessHacker 3.0, the latest version at the moment of writing, is available on the GitHub resource ([8]), the source code of additional plugins – ([9]). To build, modify, and debug the utility, Installation of the SDK and the WDK packages is needed. The Software Development Kit (SDK) is a set of tools, code samples, documentation, compilers, headers, and libraries that developers can use to create applications running on Microsoft Windows operating systems. Windows Driver Kit (WDK) is a software toolset from Microsoft that allows the development of device drivers for the Microsoft Windows platform. Building tools - MSBuild, Visual Studio 2019; build in Release mode x64 bit rate ([10-11]). There were linking errors, and the Terminator plugin project had to be excluded from the solution. To enable additional plugins, making changes to the configuration file 'ProcessHacker.exe.settings.xml', located in the \bin\Release64 directory is required ([12]).

Development of the ProcessDeepManage plugin

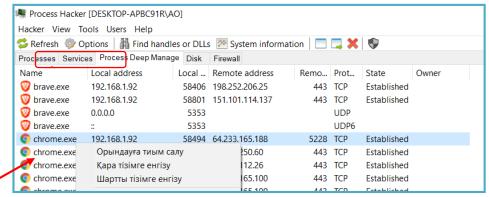

Picture 1 illustrates the code snippets for embedding the plugin in the process Hacker utility interface. The plugin is designed in the Kazakh language. Pictures 2-3 demonstrate a working plugin that is available from the context menu and in the application tabs.

```
#define PROCESSDEEPMANAGE_PLUGIN_NAME L"ProcessHacker.ProcessDeepManage"
VOID NTAPI ProcessDeepManageMenuInitializingCallback(
  _In_opt_ PVOID Parameter,
  _In_opt_ PVOID Context
                                                         PhPluginCreateEMenuItem(PluginInstance,
  PhInsertEMenuItem(menuInfo->Menu,
                                      forbidMenu
                                                                                                  0.
PROCESSDEEPMANAGE ACTION FORBID, L"&Opындауға тиым салу", ProcessDeepManageItem), 0);
  PhInsertEMenuItem(menuInfo->Menu.
                                       AddMenu
                                                         PhPluginCreateEMenuItem(PluginInstance.
                                                                                                  0.
PROCESSDEEPMANAGE ACTION Add, L"&Kapa Ti3iMTe eHri3y", ProcessDeepManageItem), 1);
  PhInsertEMenuItem(menuInfo->Menu,
                                     AddToListMenu =
                                                          PhPluginCreateEMenuItem(PluginInstance,
                                                                                                  0,
PROCESSDEEPMANAGE_ACTION_ AddToListMenu, L"&IIIартты тізімге енгізу", ProcessDeepManageItem), 2);
  PhInsertEMenuItem(menuInfo->Menu, PhCreateEMenuSeparator(), 3);
```

Pic. 1. Embedding the plugin in the process Hacker interface

Pic. 2. Menu with plugin functionality

Pic. 3. Calling the plugin functionality from the context menu

Development of a driver for the plugin

Based on the file system filter driver, a driver with the functionality described in Table 2 is made. This driver is called in the implemented ProcessDeepManage plugin. The correspondence of the menu items is also indicated in Table 1.

Table 2. Driver functionality for the ProcessDeepManage plugin

The driver's capabilities for	Action	Name of menu items
	Disable startup	Орындауға тиым салу
processes and the corresponding	Add to the prohibited list	Қара тізімге енгізу
menu items	Add to the list of conditionally allowed	Шартты тізімге енгізу
	users	

```
if (Data->Iopb->MajorFunction == IRP_MJ_CREATE)
{
    if ((Data->Iopb->Parameters.Create.SecurityContext->DesiredAccess &
        (FILE_WRITE_DATA | // 0x0002
        FILE_WRITE_ATTRIBUTES | // 0x0100
        FILE_WRITE_EA | // 0x0010
        FILE_APPEND_DATA | // 0x0004
        DELETE | // 0x00010000
        WRITE_DAC | // 0x00040000
        WRITE_OWNER // 0x00080000
        ))))
    {
        Data->Iopb->Parameters.Create.FileAttributes |= FILE_ATTRIBUTE_READONLY;
        Data->IoStatus.Information = 0;
        Data->IoStatus.Status = STATUS_ACCESS_DENIED;
        return FLT_PREOP_COMPLETE;
    }
}
```

Pic. 4. Fragment of the driver's callback function that controls the start of processes

Starting a process involves file operations. The driver implements the callback function of the filter driver, which prevents the necessary file operations. This function returns the FLT_PREOP_COMPLETE value, and setting of the STATUS_ACCESS_DENIED value of the Data->IoStatus.Status is required. A fragment of the callback function is shown in Picture 4.

In order to stop the further chain call, the value return is applied FLT_PREOP_SUCCESS_NO_CALLBACK, then the filter driver manager does not call the subsequent callback functions.

IV Results, practical significance and prospects

Thus, the results are obtained in the work:

The results of the analysis of the functionality of utilities for the administration of operating systems and computer networks will be useful in terms of selecting the optimal set of correctly working tools, as well as for identifying administrative tasks that require automation and the use of specialized programs. Classification and comparative analysis of the tasks and related administrative tools of modern Windows operating systems will be useful for operating system administrators.

For one of the popular open source utilities Process Hacker, a plugin has been developed that has added such functionality to this utility as creating and managing your own list of prohibited and conditionally allowed programs in the system and automating the management of their launch. Modification, assembly and debugging of the driver, development, testing and deployment of the plugin were performed. Based on the developed driver in the plugin, implementing for example, such interesting features as prohibiting the display of the process and changing its description in the system application "Task Manager", allowing to stop the process only after entering a password is possible. The development is directly applicable and facilitates certain tasks of administration of Windows 7 SP1, Windows 8, Windows 10.
